EKF on the flown descent (open loop) - closed_loop_imuplot.json
ACI frame, on-board gravity 'pinn', IMU ln200s (285 ug bias) @ 100 Hz, bias frame 'thrust', seed 1

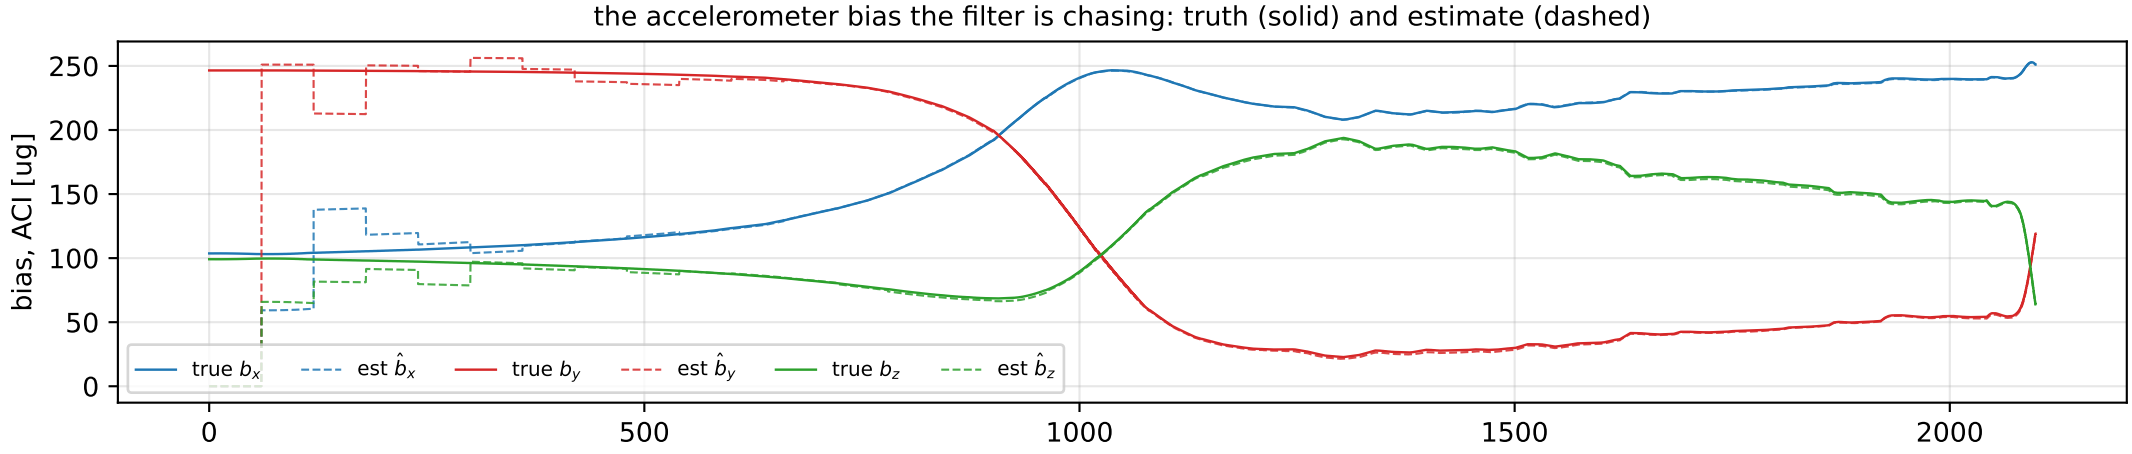

position error against the filter's own ±3σ (dashed)

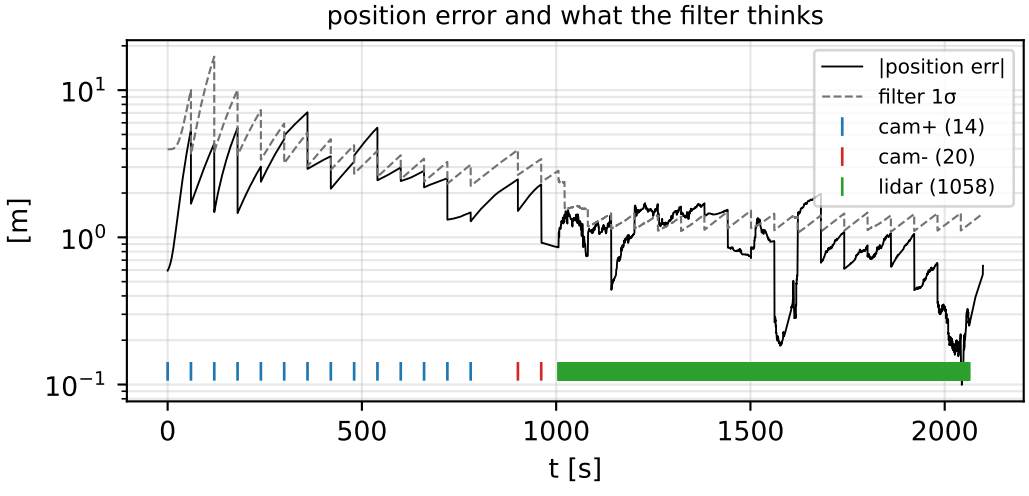

velocity error against the filter's own ±3σ (dashed)

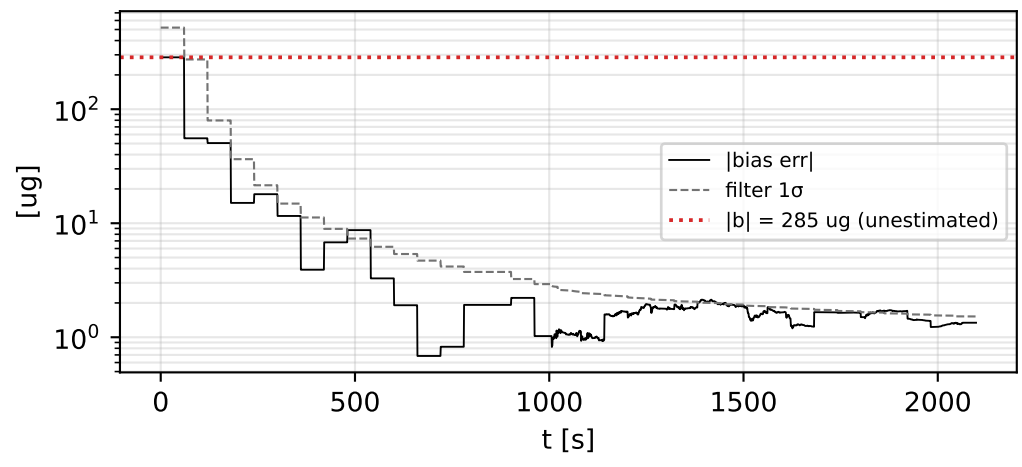

the accelerometer bias the filter is chasing: truth (solid) and estimate (dashed)

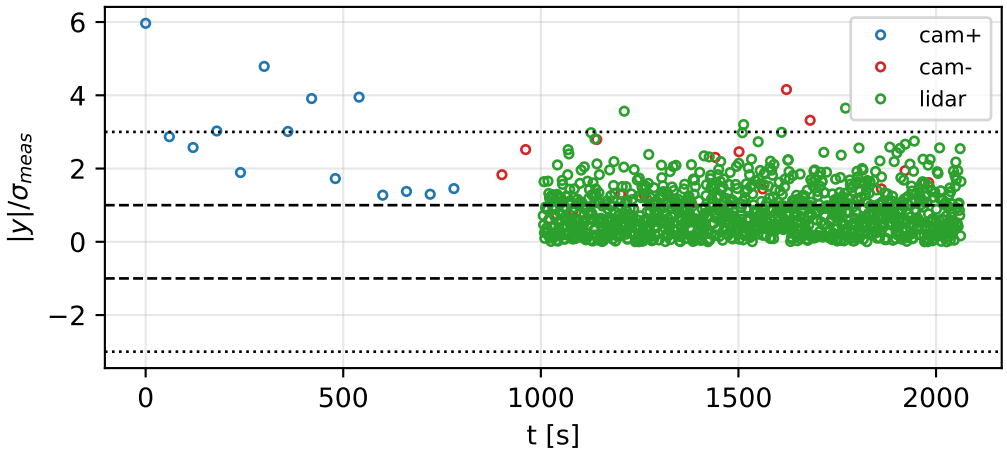

position error and what the filter thinks

does the bias become observable?

pre-fit innovations: large means the filter and the sensor disagree

consistency: above 3 means the filter is overconfident
